DEVICE FOR THE STRUCTURED STORAGE OR

HANDLING OF OPTICAL WAVEGUIDES

[0001] This National stage application claims the of International Application No. PCT/EP2003/12759, filed November 2003, on 14, claims the benefit of German Patent Application No. 10255291.6, filed on November 26, 2002 and German patent Application No. 10314262.2. The International Application was not published in the English language under PCT Article 21(2).

Field of the Invention

[0002] The invention relates to a device for the structured storage or handling of optical waveguides, especially spliced optical-fiber connections, according to the precharacterizing clause of patent claim 1.

Background of the Invention

A device for the structured storage or handling of optical waveguides of spliced optical-fiber or connections, to be specific cable sleeves, is used in fiber-optic cable networks for protecting spliced connections at connecting points of two fiber-optic cables and also for protecting the optical waveguides or optical fibers at branching points or dividing points of fiber-optic cables. In these cases, the cable sleeves must ensure the continuity of the fiber-optic cables as though the fiber-optic cables were not interrupted. structured storage and careful handling of the optical fibers or of the spliced optical-fiber connections is of significance decisive here, in order transmission properties of the optical fibers are not adversely affected.

[004] A large number of cable sleeves are known from the prior art. Reference can be made for example to EP 1 095 303 B1 as prior art. In this document, a device formed as a hood-type sleeve is known for the structured storage or handling of optical waveguides, to be specific of spliced optical-fiber connections.

[0005] Against this background, the present invention is based on the problem of providing a novel device for the structured storage or handling of optical waveguides, especially of spliced optical-fiber connections.

[0006] This problem is solved by the device mentioned at the beginning for the structured storage or handling of optical waveguides, especially of spliced optical-fiber connections, in which fiber guiding elements for optical fibers are fastened at least to one vertically running narrow side of the frame in such a way that the optical fibers are guided laterally next to the splice cases or laterally next to the frame in the region of the or each narrow side.

[0007] Preferably, the fiber guiding elements arranged in the region of the or each narrow side form at least two vertically running guiding channels for optical fibers, a first guiding channel being assigned to the front side of the frame and a second guiding channel being assigned to the rear side of the frame. Each of the guiding channels is subdivided into two guiding channel compartments in each case in such a way that at least two vertically running guiding channel compartments

E-HE-0039

respectively extend in the region of the front side of the frame and in the region of the rear side of the frame, to be specific in each case at least one inner guiding channel compartment and at least one outer guiding channel compartment. This makes particularly structured handling of the optical fibers possible.

[0008] According to an advantageous development of this first aspect of the invention concerned here, the two guiding channels running in the region of the or each narrow side are spatially separated from one another by at least one vertically running separating wall, the separating wall having an aperture in a lower portion, so that the optical fibers can be diverted from the first guiding channel into the second guiding channel, and consequently from the front side to the rear side of the frame.

The guiding channel compartments running in the region of the front side and in the region of the rear side of the frame, that is the inner guiding channel compartment and the outer guiding channel compartment, are separated from one another by a number of separating spaced apart from one another. respectively being formed between two neighboring separating webs'in such a way that the optical fibers in the region of the front side and in the region of the side of rear the frame can be diverted from the respective inner guiding channel compartment into the respective outer guiding channel compartment.

E-HE-0039

[0010] According to a second aspect of the invention concerned here, the device mentioned at the beginning for the structured storage or handling of optical waveguides, especially of spliced optical-fiber connections, provided in which a drawer that is guided in the frame can be pulled out in the horizontal direction from a first vertically running narrow side of the frame, the drawer being arranged in the pushed-in position between the splice cases assigned to the front side and the splice cases assigned to the rear side of the frame, and the drawer serving for the storage of uncut multifiber buffer tubes of optical fibers. This first narrow side lies opposite a second vertically running narrow side of the frame, to which the fiber guiding elements for the optical fibers are fastened.

According to a third aspect of the invention concerned here, the device mentioned at the beginning for structured storage of spliced optical-fiber connections is provided in which quiding channels and/or guiding ribs are arranged within the splice cases in such a way that the optical fibers are guided within the in circular splice cases a manner. This makes particularly careful handling of the optical fibers possible in the splice cases.

[0012] According to a further aspect of the invention concerned here, the device mentioned at the beginning for the structured storage or handling of optical waveguides, especially of spliced optical-fiber connections, is provided in which the optical fibers are guided by cylindrical axial bodies of the splice cases in such a

E-HE-0039

way that a direction of insertion of the optical fibers into a splice case runs approximately parallel to a pivoting axis of the respective splice case, the cylindrical axial body of the respective splice case being radially slit in such a way that the optical fibers can be inserted into the cylindrical axial body in the radial direction through a radial opening.

[0013] Additional aspects and alternative embodiments of the invention will be apparent from the appended claims, drawing figures and the description which follows.

Brief Description of the Drawings

[0014] Exemplary embodiments of the invention are explained in more detail on the basis of the drawings, without being restricted to these. In the drawings:

Detailed Description of the Invention

[0047] With reference to Figures 1 to 32, invention is described in detail below on the basis of a device formed as a hood-type sleeve for the structured storage or handling of optical waveguides, to be specific of spliced optical-fiber connections. Figures 1 to 22 relate to a first exemplary embodiment of the invention, Figures 23 to 32 relate to a second embodiment of the hood-type sleeve according to the invention. the invention can be used especially advantageously in the case of hood-type sleeves, the invention can also be used in the case of other types of sleeve, for example so-called inline sleeves.

E-HE-0039

Firstly, the exemplary embodiment according to Figures 1 to 22 is described. Figure 1 shows a hood-type sleeve 30 according to the invention, with the covering In the case of such a hood-type sleeve sleeve removed. 30, fiber-optic cables (not represented) are inserted into the hood-type sleeve 30 from below. The insertion of the fiber-optic cables into the hood-type sleeve 30 takes place via a sealing body 31. Provided in the sealing body 31 are openings 32 (see in particular Figure 2), through which the fiber-optic cables to be spliced to one another are inserted into the hood-type sleeve 30. The openings 32 for inserting the fiber-optic cables into the hood-type sleeve 30 operate on the principle of glands. The construction and operating principle of such sealing bodies 31 are quite familiar to the person addressed here and therefore need further no explanation.

[0049] Fastened to the sealing body 31 is a U-shaped bracket 33. The U-shaped bracket 33 engages with two vertically running legs 34, to be specific with end portions of these legs 34, into lateral recesses 35 of the sealing body 31. The two vertically running legs 34 of the bracket 33 are connected to one another by a horizontally running leg 36. The leg 36 accordingly extends at a vertical distance from the sealing body 31 between the two recesses 35 of the same.

[0050] Mounted on the horizontally running leg 36 of the bracket 33 is a frame 37 (see in particular Figure 2). The frame 37 is substantially formed by four vertically running frame parts 38 and two horizontally

E-HE-0039

parts 39. As Figure 2 reveals, running frame horizontally running frame part 39 respectively extends at an upper end and at a lower end of the frame 37. both sides of the horizontally running frame parts 39 there respectively extend two vertically running frame The horizontally running frame parts 39 are parts 38. formed as U-sections and the vertically running frame parts 38 are formed as L-sections. On each side of the horizontally running frame parts 39, one of the vertically running frame parts 38 accordingly respectively on the two U-legs running parallel to one Ιt follows directly from this vertically running frame parts 38 arranged in the region of one side of the horizontally running frame parts 39 are spaced apart from one another. The distance is thereby defined by the width of the horizontally running frame parts 39 formed as U-sections.

[0051] A frame 37 formed in this way has a front side 40 and a rear side 41. Both in the region of the front side 40 and in the region of the rear side 41, two vertically running frame parts 38 are respectively arranged, laterally bounding the front side 40 and the rear side 41. Furthermore, the frame 37 has a total of four narrow sides, to be specific two horizontally running narrow sides 42 and two vertically running narrow sides 43.

[0052] The horizontally running narrow sides 42 are defined by the horizontally running frame parts 39. The vertically running narrow sides 43, on the other hand, are defined by in each case two neighboring, vertically

E-HE-0039

running frame parts 38, which are fastened to one end of the horizontally running frame parts 39, to be specific to opposite legs of the horizontally running frame parts 39 formed as U-sections.

[0053] As already mentioned, the vertically running frame parts 38 are formed as L-sections. With a first leg 44, the vertically running frame parts 38 formed as L-sections are fastened to the horizontally running frame Second legs 45 of the vertically running frame parts 39. 38 are angled away from the legs approximately 90°. As Figure 2 reveals, openings 46 are provided on the one hand in the first legs 44 openings 47 are provided on the other hand in the second legs 45.

According to Figure 3, guides or holders 48 for splice cases 49 are latched in the openings 47 of the second legs 45 of the vertically running frame parts 38, formed as L-sections. The splice cases 49 are represented in Figure 3, but are for example in Figures 1, 6 or 7. The holders 48 for the splice cases 49 are provided both on the front side 40 and on the rear side 41 of the frame 37. A splice case 49 can be mounted in two holders 48, which lie opposite one another at the same height either on the front side 40 or on the rear side of the frame 37. Figure 1 in particular therefore reveals that both on the front side 40 and on the rear side 41 of the frame 37 there are accordingly a number of splice cases 49 respectively arranged one above the other. The guides or holders 48 for the splice cases 49 allow pivoting of the splice cases 49 about a pivot

E-HE-0039

axis formed by the respective holders 48. This is revealed in particular by Figure 6, which shows six swung-down splice cases 49 and a number of swung-up splice cases 49 on the front side 40 of the frame 37. The guides or holders 48 for the splice cases 49 are formed as cylindrical sections.

[0055] Figure 4 shows the frame 37 together with the holders 48 for the splice cases 49 fastened to the frame 37, and with fiber guiding elements 50 additionally fastened to the frame 37. The configuration and arrangement of the fiber guiding elements 50 constitutes a first aspect of the invention concerned here.

Figure 4 in particular reveals that the fiber [0056] guiding elements 50 are assigned to one of the vertically running narrow sides 43 of the frame 37. The fiber guiding elements 50 are pushed onto the legs 44 of the vertically running frame parts 38, formed as L-sections, in the region of this one vertically running narrow side 43, to be specific they are pushed on by means of barblike anchoring elements 51, which latch into clearances 46 in the region of the legs 44. The fiber quiding elements 50 are accordingly arranged exclusively in the region of one of the vertically running narrow sides 43 of the frame 37.

[0057] As each of Figures 4 to 9 reveals, the fiber guiding elements 50 form two vertically running guiding channels 52 and 53. A first guiding channel 52 is assigned to the front side 40 of the frame 37. A second guiding channel 53 is assigned to the rear side 41 of the

E-HE-0039

frame 37. This can be seen best from Figure 7. The two vertically running guiding channels 52 53 and separated from one another by a likewise vertically running separating wall 54. As revealed in particular by Figures 5 and 6, the separating wall 54 is provided in a lower portion with an aperture 55. The significance of the aperture 55 is discussed in greater detail further below. Therefore, laterally next to the vertically running narrow side 43 of the frame 37 there extend the two vertically running guiding channels 52 and 53; the first guiding channel 52 is assigned to the front side 40 of the frame 37 and the second guiding channel 53 is assigned to the rear side 41 of the frame 37.

Furthermore, each of Figures 4 to 9 reveals [0058] that each of the two vertically running guiding channels 52 and 53 is subdivided into two likewise vertically running guiding channel compartments in each case, to be specific an inner guiding channel compartment 56 and an outer guiding channel compartment 57. In the region of the front side 40, to which the first guiding channel 52 is assigned, there accordingly runs an inner guiding channel compartment 56 and an outer guiding channel compartment 57. Likewise, in the region of the rear side 41 there runs an inner quiding channel compartment 56 and an outer guiding channel compartment 57. It follows from this that the separating wall 54 separates the two inner guiding channel compartments 56 from one another. The separation of the inner guiding channel compartments 56 from the outer guiding channel compartments 57 in the region of the front side 40 and in the region of the rear of the frame 37 takes place by means of side 41

E-HE-0039

58. Therefore, separating webs а number of separating webs are positioned over the entire height of the frame 37, apertures 59 being formed respectively between two neighboring separating webs 58. It follows from this that, in the region of the separating wall 54 which separates the two guiding channels 52 and 53 from one another, only one aperture 55 is positioned provided in a lower portion of the separating wall 54. For the separation of the inner guiding channel compartments 56 from the guiding outer channel compartments 57, however, a number of apertures 59 provided over the entire height of the frame 37. significance of the apertures 59 between the separating webs 58 will be discussed in greater detail below. As revealed in particular by Figure 7, accordingly four guiding channel compartments 56 and 57, respectively, are positioned in a plane next to one specific laterally next to the to be vertically running narrow side 43 of the frame 37.

[0059] The fiber guiding elements 50 form not only the vertically running guiding channels 52, 53, but also curved guiding channels 60 for optical fibers. This can be seen for example in Figure 4. The curved guiding channels 60 open out on the one hand into the outer guiding channel compartments 57 and on the other hand into the holders 48, formed as cylindrical hollow bodies, for the splice cases 49. The significance of the curved guiding channels 60 will likewise be discussed in greater detail further below.

E-HE-0039

As Figure 5 in particular reveals, a directing device or fixing device 61 for multifiber buffer tubes is arranged in a lower portion of the frame 37, that is in the region of the bracket 33. This directing device or fixing device 61 for the multifiber buffer tubes has a number of directing channels 62. The directing channels 62 all have a curved profile and end in the region of the vertically running narrow side 43 on which the fiber quiding elements 50 are arranged and on which vertically running guiding channels 52, 53 are formed. In a lower portion of the guiding channels 62, the same are facing the sealing body 31, and consequently the openings 32 within the sealing body 31. In the case of the exemplary embodiment according to Figures 1 to 22, the directing channels 62 accordingly all lie in one plane and end in the region of a vertically running narrow side 43.

[0061] Positioned above the guiding channels 62 and beneath the lowermost holders 48 for the splice cases 49 is a plate-shaped element 63 with a stop 64 for the lowermost splice case 49. As Figure 7 in particular reveals, the lowermost splice case 49 rests on the stop 64 in the swung-down or pivoted-down position. As a result, the approximately 45° sloping inclination of the splice cases 49 that is represented in Figure 7 is obtained in the swung-down position.

[0062] As already mentioned several times, fiber-optic cables to be connected are inserted through the openings 32 of the sealing body 31 into the hood-type sleeve 30. A number of multifiber buffer tubes are positioned in

E-HE-0039

such fiber-optic cables, preferably twelve optical fibers being arranged within one multifiber buffer tube. shows a number of multifiber buffer tubes 65 with optical fibers 66 arranged in the multifiber buffer tubes The fiber-optic cable as such is not shown in Figure 8. The multifiber buffer tubes 65 are inserted via the of the directing 62 portions channels in approximately parallel alignment in relation to one another into the directing channels 62 of the fixing device 61. As soon as the multifiber buffer tubes 65 have been inserted into the directing channels 62 of the fixing device 61, the multifiber buffer tubes preferably also fixed to the directing channels 61 by means of cable ties that are not represented. following this, jackets are removed from the multifiber buffer tubes 65 and only the individually separated optical fibers 66 are quided. Therefore, Figure 8 reveals that all the optical fibers 66 guided in the multifiber buffer tubes 65 are guided via the directing channels 62 into the region of the vertically running narrow side 43 of the frame 37 in which the fiber guiding elements 50 are positioned. The optical fibers 66 are accordingly directed into the region of the vertically running guiding channels 52 and 53 and are accordingly quided exclusively in the region of the vertically running narrow side 43 laterally next to the splice cases 48 in which the fiber guiding elements 50 are positioned.

[0063] At the transition of the optical fibers 66 from the fixing device 61 into the fiber guiding elements 50, it must be decided whether an individual optical fiber 66 is fed to a splice case 49 in the region of the front

E-HE-0039

side 40 or in the region of the rear side 41. aperture 55 in the separating wall 54 is significant in this connection. The aperture 55 accordingly serves for deflecting the optical fibers 66 out of the region of the front side 40 into the region of the rear side 41 or out of the region of the rear side 41 into the region of the front side 40. Directly after the optical fibers 66 have accordingly left the directing channels 62 of the fixing device 61, it is decided whether the optical fibers 66 are fed to the vertically running guiding channel 52 in the region of the front side 40 or to the vertically running guiding channel 53 in the region of the rear side 41. The deflection of optical fibers 66 in the region of the aperture 55 of the separating wall 54 can be clearly seen in particular in Figure 7.

[0064] it Once has been established whether optical fibers 66 are guided in the guiding channel 52, assigned to the front side 40, or in the guiding channel 53, assigned to the rear side 41, and ultimately are fed to the splice cases 49, all the optical fibers 66 in the region of a guiding channel 52 or 53 are initially guided the inner guiding channel compartment 56 of respective guiding channel 52 or 53. The optical fibers 66 are guided in the inner guiding channel compartment 56 until they reach the height at which the splice case 49 to which the corresponding optical fiber 66 is to be fed is positioned. Once the corresponding height has been the corresponding optical fibers are deflected out of the inner guiding channel compartment 56 via the apertures 59 in the region of the separating webs 58 into the outer guiding channel compartment 57.

E-HE-0039

can be seen particularly clearly in Figures 7 and 9 for Once the optical fibers 66 have reached the corresponding height of the splice case 49 into which the optical fibers 66 are to be inserted, the optical fibers 66 accordingly run for the first time in the outer guiding channel compartment 57. From the outer guiding channel compartment 57, the optical fibers are inserted into the curved guiding channel 60, interacts with the holder 48 of the corresponding splice case 49. This can be seen in detail in particular in Figure 9 and Figure 14.

100651 The configuration according to the invention accordingly makes particularly structured and careful storage or handling of optical fibers possible within a cable sleeve. Once they have been individually separated from the multifiber buffer tubes 65 by removing the jacket from the buffer tubes 65, the optical fibers 66 are initially guided into the region of one side of the splice cases 49. The optical fibers 66 are exclusively guided to one side of the splice cases 49 or to one side of the frame 37 in vertically running guiding channels 52 Directly after all the optical fibers 66 have and 53. been guided into the region of this one side, the optical fibers are fed either to a guiding channel 52 assigned to the front side 40 of the frame 37 or to a guiding channel 53 assigned to the rear side 41 of the frame 37 and are quided vertically upward. Within these two quiding channels 52 and 53, the optical fibers 66 run initially in the region of the inner guiding channel compartments 56, until the height of the splice cases 49 into which the respective optical fiber 66 is to be inserted is

E-HE-0039

reached. Once this height is reached, the optical fibers 66 are transferred into the region of the outer guiding channel compartment 57 and then ultimately threaded into the curved guiding channel 60, which feeds the optical fiber 66 to a splice case 49.

[0066] The splice cases 49 are clipped into the holders 49 by means of cylindrical axial bodies 67. This is revealed in particular by Figure 6. The cylindrical axial bodies 67 of the splice cases 49 are represented in greater detail in Figures 10 to 12. Furthermore, these details are revealed in Figures 17 and 18.

[0067] The cylindrical axial bodies 67 of the splice cases 49 are formed as hollow cylinders. The optical fibers 66 are guided through the cylindrical axial bodies 67 for insertion of the same into a splice case 49, to be precise in such a way that a direction of insertion of optical fibers 66 into a splice case approximately parallel to a pivot axis of the respective splice case 49 defined by the axial bodies 67. guidance of an optical fiber 66 through the cylindrical axial bodies 67 parallel to the pivot axis of the splice case 49 can be seen particularly well in Figure 18. significance in this connection that the cylindrical axial bodies 67 are axially slit, that is have an opening 68 in the radially outward direction. The opening 68 in the region of the cylindrical axial bodies 67 can be seen for example in Figure 10. optical fibers 66 can be inserted in the radial direction into the cylindrical axial bodies 67 via the opening 68. As a result, particularly simple and careful insertion of

E-HE-0039

the optical fibers 66 from the curved guiding channels 60 into the splice case 49 is made possible.

[0068] · In order then to ensure that the optical fibers 66 placed into the cylindrical axial bodies 67 cannot out from the cylindrical axial bodies 67, particular during the pivoting of the splice cases 49, damaged thereby, guiding be webs 69, 70 integrated in the splice case 49 (see in particular Figures 10 and 11). As revealed in particular by Figure 19, the guiding webs 69, 70 are integrated in the splice case 49 in such a way that, in projection, one of the guiding webs 69, 70 covers the opening 68 in the axial cylinder 67 in every position of the splice case 49. optical fibers 66 always lie against an inner wall 71 of the cylindrical axial body 67 lying opposite the opening It is accordingly ensured as a result that the optical fibers 66 always remain inside the axial body 67 during the pivoting of the splice case 49, and cannot Furthermore, laterally next to the jump out from it. curved channels 60 in the region of the outer guiding channel compartments 57 are guiding webs 72, likewise serve for the quidance of the optical fibers 66 (see in particular Figures 14, 15, 16 and 18). guiding webs 72 in the region of the outer guiding channel compartments 57 prevent the optical fibers from falling out from the outer guiding channel compartments Furthermore, the guiding webs 72 also have the in the region of the outer guiding channel compartments 57 that the optical fibers 66 lie against the inner wall 71 of the cylindrical axial body 67. can be seen in particular in Figure 20. This is the case

E-HE-0039

because an inner wall of the guiding web 72 is rearwardly or inwardly offset with respect to the inner wall 71 of the cylindrical axial bodies 67, so that the slightly curved or slightly rearwardly or inwardly bent profile of the optical fibers 66 that is represented in Figure 20 is obtained.

[0069] A further aspect of the invention concerned here relates to the guidance of the optical fibers 66 within the splice cases 49. The optical fibers 66 running in the splice cases 49 are therefore curved in a circular manner within the splice cases 49. The circular guidance of the optical fibers 66 has the advantage that the same are subjected to minimized mechanical loading. The transmission properties of the optical fibers 66 are then not adversely influenced.

To ensure the circular guidance of the optical [0070] fibers 66 within the splice cases 49, a number of quiding channels or quiding ribs are integrated in the splice 49. therefore cases Figure 11 shows two semicircular guiding ribs 73 and also guiding ribs 74, which are arranged in a central portion of the splice cases 49 and the outer contour of which likewise defines, at least in certain portions, a segment of a circle. Therefore, in the case of the exemplary embodiment of Figure 11, a total of four guiding ribs 74 are arranged in the central portion of the splice cases 49. outer edges of the guiding ribs 74 define segments of a circle of different sizes. Circular guiding channels 75 are formed between the quiding ribs 74 arranged in the central region of the splice case 49.

E-HE-0039

It can be seen from Figures 12 and 13 that the guiding ribs 73 and the guiding ribs 74 form three interlinked and overlapping circular guides 76, 77 and 78. The circular guides 76, 77 and 78 are in this case aligned in relation to one another in such a way that the two outer circular guides 76 and 78 touch in the central portion of the splice cases 49 and merge tangentially with each other. In this region, a change in the radius of curvature can then be realized for the Furthermore, the circular guides 76, optical fibers 66. 77 and 78 are aligned in relation to one another in such a way that the optical fibers 66 can be quided in a circular manner in the splice case with approximately the same radii, irrespective of their length. This makes it possible to provide circular quidance for any desired length of optical fibers 66 within the splice cases 49, maintaining the ideal bending consequently careful handling of the optical fibers 66. Figure 12 shows for example that, in the sense of a circular guide 79, an oval guidance of the optical waveguides is also possible, the oval circular guide 79 being composed of the circular guides 76 and 78. also of significance in this connection that a stowage space 80 for excess lengths of the optical fibers 66 is created between the outer guiding ribs 73 and the inner quiding ribs 74. The actual length compensation for the optical fibers takes place within the stowage space 80, since the oval circular guide 79 may be pronounced to a greater or lesser extent within the stowage space 80.

E-HE-0039

[0072] Figures 14 to 16 show optical fibers 66, which are guided in different ways within the splice cases 49. For instance, Figure 16 shows a number of optical fibers 66 which are guided on the one hand in an oval manner and on the other hand in a circular manner. Furthermore, Figure 14 shows a splice 81 between two optical fibers 66 to be connected, which is stored in a region of the splice case 49 specifically provided for this purpose. Within such a splice case 49, a total of four such cable splices 81 can be stored.

[0073] According to a further aspect of the invention concerned here, a drawer 82 which can be pulled out from the frame 37 and is intended for the storage of uncut multifiber buffer tubes 65 is integrated in the frame 37 of the hood-type sleeve 30. The drawer 82 is integrated between the vertically running frame parts 38 of the frame 37 in the latter and can be pulled out from the frame 37 in a horizontal direction. The drawer 82 is thereby pulled out from the frame 37 to the vertically running narrow side 43 thereof which lies opposite from the vertically running narrow side 43 to which the fiber guiding elements 50 are fastened. Accordingly, optical fibers 66 are guided in the region of the fiber guiding elements 50 to one side of the frame 37 or to one side of the splice case 49. To the opposite narrow side 43, the drawer 82 can be pulled out from the frame 37. Figure 1 shows the drawer 82 in a position in which it is pushed into the frame 37, Figure 21 shows it in a position in which it is pulled out from the frame 37. Figure 22 shows uncut multifiber buffer tubes 65 stored in the drawer 82.

E-HE-0039

To be able to grip the drawer 82 for pulling it out from the frame 37, in the exemplary embodiment shown actuating grips 83 are provided on a vertically running The actuating grips 83 serve at side of the drawer 82. the same time for the secure guidance of the multifiber buffer tubes 65 within the drawer 82. In addition to the 83, 84 actuating grips quides are provided horizontally running sides of the drawer 82. The quides 84 also serve for the secure storage of the multifiber buffer tubes 65 within the drawer 82.

accordance with [0075] Ιn the first exemplary embodiment according to Figures 1 to 22 of the invention concerned here, a hood-type sleeve 30 is accordingly proposed, within which sleeve all the optical fibers 66 are guided to a side next to the stack of splice cases 49 once said fibers have been individually separated from the multifiber buffer tubes 65 in the region of fixing device 61 by removal of the buffer tube jacket. The optical fibers 66 are accordingly guided vertically upward exclusively to one side of the stack of splice cases 49. Provided for this purpose on this one side are fiber guiding elements 50, which both in the region of the front side 40 and in the region of the rear side 41 the frame 37 provide vertically running channels 52, 53, which are respectively subdivided into an inner guiding channel compartment 56 and an outer guiding channel compartment 57. Furthermore, it is in keeping with the invention to guide the optical fibers 66 out of the outer guiding channel compartments 57 into curved guiding channels 60 in such a way that the optical

E-HE-0039

fibers 66 are guided through cylindrical axial bodies 67 of the splice cases 49 and are therefore directed into the interior of the splice cases 49. The optical fibers 66 are prevented from jumping out from the cylindrical axial bodies 67, to be specific from a radial opening 68 of the axial bodies, by guiding webs 69, 70 integrated in the splice cases 49. Within the splice cases 49, the optical fibers 66 are guided in a circular manner. Also provided is a drawer 82 for the storage of multifiber buffer tubes, which can be pulled out from the frame 37 to a side which is opposite from the side to which the fiber guiding elements 50 are fastened. splice cases 59 can be fastened into the holders 48 independently of the fiber guiding elements 50. produces a modular construction of the device according to the invention.

The above aspects of the design with respect to Figures 1 to 22 all relate to the hood-type sleeve 30 according to the first exemplary embodiment the invention. Α second exemplary embodiment of the invention is described below with reference to Figures 23 The second exemplary embodiment according to Figures 23 to 32 also relates to a hood-type sleeve 85. In the aspects concerning the basic structural design, hood-type sleeve 85 of the second embodiment according to Figures 23 to 32 coincides with the hood-type sleeve 30 of the first exemplary embodiment according to Figures 1 to 22. To avoid unnecessary repetition, the same reference numerals are therefore used for the same subassemblies. Only the differences which differentiate the hood-type sleeve 85 according to

E-HE-0039

the second exemplary embodiment as shown in Figures 23 to 32 from the hood-type sleeve 30 of the first exemplary embodiment as shown in Figures 1 to 22 are discussed below.

[0077] A first basic difference between the hood-type sleeve 85 according to the second exemplary embodiment of the invention and the hood-type sleeve 30 according to the first exemplary embodiment of the invention is that the drawer has been omitted in the case of the hood-type sleeve 85. In the case of the hood-type sleeve 85 according to the second exemplary embodiment of invention, fiber guiding elements 50 in keeping with the invention extend to both vertically running narrow sides 43 of the frame 37. This can be seen in particular from Figures 23 and 24. It follows directly from this that guiding channels 52 and 53 are formed in the region of the two vertically running narrow sides 43. these guiding channels 52 and 53 is in turn subdivided into guiding channel compartments, to be specific into inner guiding channel compartments 56 and outer guiding channel compartments 57. Laterally next to the two vertically running narrow sides 43, and consequently to both sides of the splice cases 49, there accordingly extend in each case four guiding channel compartments 56 and 57, respectively, positioned in a plane next to one another.

[0078] As revealed in particular by Figures 23 to 25, a second difference between the hood-type sleeve 85 according to the second exemplary embodiment of the invention and the hood-type sleeve 30 according to the

E-HE-0039

first exemplary embodiment of the invention is that the guiding channels 52 and 53 running in the region of the two vertically running narrow sides 43 are not separated another merely by one vertically separating wall, but rather by two vertically running separating walls 86 and 87, the two separating walls 86 being spaced and 87 apart from one another and accordingly bounding a receiving space 88. This receiving space 88 can best be seen in Figure 25. Uncut multifiber buffer tubes can be inserted into receiving space 88. The receiving space 88 of the hoodsleeve 85 according to the second exemplary embodiment of the invention as shown in Figures 23 to 32 accordingly undertakes the function of the drawer 82 of the hood-type sleeve 30 according to the first exemplary embodiment of the invention as shown in Figures 1 to 22.

[0079] As likewise revealed by Figures 24 and 25, the separating walls 86 and 87, otherwise running parallel to one another and spaced apart from one another, touch in a lower portion to form the aperture 55. The aperture 55 serves in turn the purpose of deflecting optical fibers from the front side 40 into the region of the rear side 41 or from the region of the rear side 41 into the region of the front side 40.

[0080] A further difference between the two exemplary embodiments relates to the design of the directing device or fixing device 61 for the multifiber buffer tubes. This is revealed in particular by Figures 23 to 25. As a difference from the hood-type sleeve 30 according to the first exemplary embodiment of the invention, guiding

E-HE-0039

channels or directing channels 89 formed by the directing device or fixing device 61 do not all lie in one plane in the case of the hood-type sleeve 85 of the second exemplary embodiment of the invention according Figures 23 to 32. The directing channels 89 also do not all end and/or open out in the region of a vertically running narrow side 43, but half of the channels 89 open out in the region of a first vertically running narrow side 43 and the other half directing channels 89 open out in the region of second vertically running narrow side 43. As already mentioned, this is so because, in the case of the hoodtype sleeve 85 according to the second embodiment of the invention the optical fibers are guided upward laterally next to the splice cases 49 in the region of both vertically running narrow sides 43. it is advantageous for this exemplary this extent. embodiment that the directing channels 89 also end in the region of the two vertically running narrow sides 43.

[0081] In order to guide optical fibers which either in the region of the front side 40 or in the region of the rear side 41 from the guiding channels 52 or 53 in the region of a first vertically running narrow side 43 into the region of the guiding channels 52 or 53 of the second vertically running narrow side 43, in the case of the exemplary embodiment of Figures 23 to 32 two deflecting cylinders 90 and 91 are respectively provided in the region of the plate-shaped element 63, both in the region of the front side 40 and in the region of the rear side 41. The deflecting cylinders 90 and 91 can best be 23. seen from Figure Optical fibers which

E-HE-0039

accordingly to be guided from one vertically running narrow side 43 into the region of the other vertically running narrow side 43 can accordingly be guided back and forth by means of the deflecting cylinders 90 and 91 in a simple and careful manner, while conforming to the permissible minimum bending radii. It should also be pointed out that the deflection from the front side 40 to the rear side 41 or from the rear side 41 to the front side 40 takes place via the apertures 55, which are arranged laterally next to the vertically running narrow sides 43 in the region of the guiding channels 52 and 53.

[0082] Α further difference between the hood-type sleeve 30 according to the first exemplary embodiment of the invention and the hood-type sleeve 85 according to the second exemplary embodiment of the invention relates to the structural design of the splice cases 49. splice cases 49 of the hood-type sleeve 85 according to the second exemplary embodiment of the invention are shown most clearly in Figures 24 and 26. The splice cases 49 of the hood-type sleeve 85 according to the second exemplary embodiment of the invention also allow circular guidance of the optical fibers in the form of three interlinked and overlapping circular guides, as has been explained in the case of the first exemplary embodiment in connection with Figure 13. A difference between the splice cases can be seen, however, in the design or configuration of the quiding ribs. The splice 49 of the second exemplary embodiment of invention has in turn two outer semicircular and web-like guiding ribs 73, but the flat guiding ribs 74 have been omitted. Rather, web-like guiding ribs 92 are present in

E-HE-0039

the central portion of the splice case 49 of the second exemplary embodiment. In a way similar to the web-like guiding ribs 73, the web-like guiding ribs 92 define in certain portions a segment of a circle. In the case of the splice cases 49 of the second exemplary embodiment of the invention, however, guiding channels between the guiding ribs 92 arranged in the central region of the splice case 49 have been omitted.

[0083] This is advantageous with regard to the guidance of the optical fibers. Furthermore, the weblike formation of the guiding ribs 92 in the central region of the splice case 49 produces a saving of material, and consequently a weight reduction.

Figure 31 shows a further difference, relating splice case, between the two It can be seen in Figure 31 that splice embodiments. cases 49 of different thicknesses can be used. According to Figure 31, the splice cases 49 in the region of the front side 40 are twice as thick as the splice cases 49 in the region of the rear side 41 of the hood-type sleeve In the splice cases 49 of twice the thickness or height, a greater number of spliced connections can be stored. It is a special feature of the structural design principle of the invention concerned here that cases of different thicknesses or heights can interchanged in a simple manner, without making any further structural design modifications to the sleeve. If splice cases 49 of twice the thickness or height are used, only every second holder 48 is used for the splice cases 49. Two holders 48 which lie opposite one another

E-HE-0039

at the same height then in turn form a pivot axis for the splice case 49. The holders positioned directly above and beneath the holders 48 forming a pivot axis remain free when a splice case 49 of twice the height or thickness is used. Accordingly, no structural design modifications have to be made to the holders for the splice cases.

A further difference between the two exemplary embodiments of the invention concerned here relates to the securement of the optical fibers 66 placed into the cylindrical axial bodies 67 of the splice cases 49 to prevent them jumping out from the cylindrical bodies 67 during a pivoting movement of the splice cases Thus coinciding with the first exemplary embodiment according to Figures 1 to 22, the guiding webs 69 and 70 are in turn integrated in the splice case 49 in the case of the second exemplary embodiment according to Figures 23 to 32. This can be seen most clearly in Figures 28 to 30. In the case of the second exemplary embodiment according to Figures 23 to 32, however, the guiding channels 52 and 53, and consequently the outer guiding channel compartments 57, are offset outward to form the receiving space 88, so that the function of the guiding web 72 described in the case of the first exemplary embodiment according to Figures 1 to 22 is no longer effective in the region of the outer quiding channel compartment 57. In order to compensate for this, in the case of the second exemplary embodiment according to Figures 23 to 32 guiding ribs 93 are provided in the region of the curved guiding channels 60, to be specific neighboring the holders 48 for the axial bodies 67 of the

E-HE-0039

splice cases 49. The guiding ribs 93 can be seen most The guiding ribs 93 protrude clearly in Figure 29. alternately in the upward and downward directions, optical fibers 66 being guided in a groove-like recess 94 within the guiding ribs 93. Accordingly, if the splice case 49 is turned, the optical fiber 66 always remains within the recess 94 and accordingly always constantly against the guiding rib 93. Jumping out of the optical fiber 66 from the opening 68 inside the axial body 67 is thereby avoided.

[0086] Figure 32 further detail shows a invention concerned here which can be used both in the case of the exemplary embodiment according to Figures 1 22 and in the case of the exemplary embodiment according to Figures 23 et seq. Figure 32 shows four guiding channels 89 lying next to one another in the region of the directing device or fixing device 61 for As shown in the detail the multifiber buffer tubes. according to Figure 32 and as the difference in relation to the fastening of the multifiber buffer tubes by means of cable ties that was explained in connection with the first exemplary embodiment according to Figures 1 to 22, here the fixing of the multifiber buffer tubes in the region of the guiding channels 89 takes place by means of holding plates 95. As Figure 32 reveals, guiding rails 96 into which the holding plates 95 can be pushed are provided in the region of the guiding channels 89. pushing-in of the holding plates 95 into the guiding rails 96 takes place in the sense of the arrow 97. Figure 32 reveals, a slot-like clearance is provided in the holding plate 95. If the holding plate 95 is pushed

E-HE-0039

into the corresponding guiding rails 96 in the direction of the arrow 97, a barb-like anchoring element 98, which is bounded by the slot or the clearance, is pressed inward, the anchoring element 98 snapping back again into its original position when the holding plate 95 has been pushed completely into the guiding rails 96, therefore fixing the holding plate 95 in the guiding channels 89. According to the invention, one side of the holding plate 95 is smoothly formed, whereas a separating web 99 is provided on the opposite side of the holding plate 95. A holding plate 99 accordingly serves for fixing two multifiber buffer tubes in the quiding channels 89, a buffer tube being respectively arranged to Ιf each side of the separating web 99. multifiber buffer tubes are to be fixed in the guiding channels 89 in the case of the arrangement shown in Figure 32, the buffer tubes are first placed on the smooth side of an already inserted holding plate 95, holding plate 95 pushed new is into corresponding guiding rails 96. Furthermore, it should be noted that an axial displacement of the buffer tubes is possible in the case of the fixing of the same that is shown in Figure 32.

E-HE-0039
